ABSTRACT The distribution of the ABO and Rh(D) blood groups among three different religious communities viz. Hindu, Muslim and Sikh is reported from Dhar district of Madhya Pradesh. In Hindu and Sikh allele frequencies of O group is followed by B and then A group while in Muslim O group is followed by A and then B group. Regarding Rh(D) allele frequencies D is followed by d.

Blood grouping is a valuable tool in blood transfusion, forensic medicine and in paternity disputes. Blood groups are also extensively employed to evaluate the ethnic variation and affiliation between different populations (Bhasin et al., 1994). Thus the study of blood groups has been a source of interest to pathologists, biologist, geneticists, anthropologists, statistician and human ecologists. The present investigation was undertaken to study the distribution of ABO Rh(D) blood groups among the Hindu, Muslim and Sikh of Dhar district of Madhya Pradesh.

MATERIAL AND METHODS

Blood samples were collected randomly from individuals belonging to three different religious communities viz. Hindu, Muslim and Sikh inhabiting Dhar district of the central Indian state of Madhya Pradesh. Serological tests were performed using standard antisera with proper controls. The calculations of allele frequencies of the ABO and Rh(D) blood groups following Yasuda (1984) and Mourant et al. (1976), respectively.

RESULTS AND DISCUSSION

Results are presented in tables 1 and 2. Table 1 shows that B group dominated (35%) in Hindu, while O group was found to be dominant in both Muslim (46.15%) and Sikh (33.33%). AB was the least frequent group in each of the group studied. It is also observed from the table 1 that the allele frequency of O group was higher than A and B groups in each of the group studied. In Hindu and Sikh the predominant allele frequency was B. While in Muslim the predominant allele frequency was in A group, which may be due to the heterogeneous distribution. The range of allele frequencies was 0.2086 to 0.2120 in A group, 0.1209 to 0.2450 in B group and 0.5430 to 0.6673 in O group.

The Rh(D) phenotypes and allele frequencies of the three communities studied in the present investigation (Table 2) had not shown much variation in their distribution. In all of them, group Rh(D) positive was found to be}
