ABSTRACT The present study deals with the relationship between cardiorespiratory fitness, body composition and blood pressure in Punjabi collegiate population (n = 148) aged 19 – 26 years. Height and weight were determined by kinaanthropometric methods, blood pressure was measured with subjects lying supine after at least 5 min. rest, VO$_2$ max was measured by Queen’s College Step test. The results indicated that there was a close association with VO$_2$ max and percent body fat, and systolic blood pressure in boys, but in girls, correlation was found only between VO$_2$ max and systolic blood pressure.
